MISCELLANEOUS REPORT No. 7

COMMODITY DRAIN FROM FORESTS OF THE LAKE STATES - 1946

By Arthur G. Horn, Forest Economist 1/
Lake States Forest Experiment Station 2/

INTRODUCTION

Shortly after World War II, a field survey was initiated to obtain accurate information on the forest resources of the Lake States. Collection and compilation of timber drain statistics was one of several important phases of this survey.

As a means of determining the annual drain, the Station has obtained annual or periodic reports for the principal forest industries. These reports cover either the year's production of finished products or the receipts of sawlogs and bolts at the plants. From them the Station computes commodity drain, that is, the amount of live merchantable timber removed through cutting, including logging waste, during the year.

To meet the frequent requests for production and drain data resulting from the survey, the Station has prepared a set of tables giving Lake States production and drain figures for 1946. In using the data, it is important to keep in mind the standards and definitions used in compiling the information. (See page 2).

Basis for Production Statistics

The Bureau of the Census collected and published Lake States lumber production statistics for 1946. The figures are based on a sample survey carried on in conjunction with the sawmill canvass for the 1947 Census of Manufactures. These lumber production figures and supplemental data collected by the Station to determine interstate movement of logs were used as a basis for sawlog and box-bolt production estimates.

1/ The author gratefully acknowledges the assistance provided in some of the field work by Z. A. Zasada, J. R. Neetzel, foresters of the Lake States Station, and W. S. Sands and G. R. Condit, formerly of the Lake States Station; and W. W. Barton, Forester, R-9 Regional Office. Acknowledgment is also due to the many owners and operators of wood-using mills and plants in the Lake States region who furnished the basic information necessary for this report.

2/ Maintained by U.S. Department of Agriculture, Forest Service, in cooperation with the University of Minnesota, at University Farm, St. Paul, Minnesota.

For veneer, pulpwood, distillation wood, excelsior, cooperage and miscellaneous products (matches, clothespins, bowling pins, handles, etc.) a complete canvass was made of all known plants early in 1947. The volume of logs and bolts received at these plants during the calendar year was used as a basis for production estimates.

Production statistics for such minor items as piling, poles, hewn ties and mine timbers, lagging, etc., were obtained by using results of the 1947 survey of these items and comparing them with reliable production indices for 1946-47, i.e., annual underground ore production by states, pole and piling receipts of several large wholesalers and distributors who handle most of the regional output. Because financial limitations precluded making special surveys, estimates for fuelwood, posts, and some miscellaneous items were based largely on surveys made during the latter stages of World War II. Some adjustments were made on the basis of more recent findings from wholesalers and distributors.

Conversion Factors

The Station has collected supplemental information on each product as to percent of wood volume obtained from live, dead, cull trees, and byproduct material; also proportion of volume cut from saw-timber and pole-timber trees. Gross volumes of individual products were determined by information furnished by industry. For example, stock records for posts, poles, and piling showed the number of pieces by length, top, and butt diameters. Such information made possible calculations of gross volume for each product. By incorporating these findings with data collected during a previous field survey (1936-37), a set of conversion and waste factors were prepared which are closely in line with present utilization standards of wood-using industries.

General Limitations of Data

The forest survey accuracy goal for drain data is ± 5 percent per billion cubic feet, which would permit a standard error of slightly more than 6 percent on the 1946 estimate for the Lake States. Because of the absence of an accurate survey for fuelwood for that year, the estimates presented here may not be within that limit. We feel, however, that the estimates are the best obtainable at this time and will serve a useful purpose. Figures for most products are within the proposed limits.

Survey Definitions

Commodity Production

The gross volume of a forest product made from any class of material from commercial or noncommmercial forest lands. Production has been expressed in the following standard survey units: Board-feet log scale International 1/4-inch rule; feet, board measure lumber tally; cord (4x4x8 feet), rough wood basis; number of pieces; and number of cubic feet (inside bark).

Commodity Drain

The net volume of timber removed from growing stock on commercial forest lands through cutting and logging waste during the year, expressed in board feet, International 1/4-inch rule and cubic feet (i.b.).

Drain from Saw-Timber Trees

The net volume (board feet, International 1/4-inch) of the log portion in softwood trees 9 inches and larger and hardwood trees 11 inches and larger, d.b.h., removed or wasted during logging operations. The cubic-foot volume shown includes both the saw-timber equivalent and the volume in the tops of softwood trees to a 4-inch minimum.

Drain from Pole-Timber Trees

The net volume in cubic feet (i.b.) of pole timber removed through cutting and logging waste during the year. Included in this class are softwood trees from 5.0 to 8.9 inches and hardwood trees from 5.0 to 10.9 inches d.b.h. It includes cubic-foot volume found in the tree stems to a minimum top diameter of 4 inches (i.b.).
